

# MPCxxx Instruction Set

This chapter lists the MPCxxx instruction set in alphabetical order by *mnemonic*. Note that each entry includes the instruction formats and a quick reference 'legend' that provides such information as the level(s) of the PowerPC architecture in which the instruction may be found—*user instruction set architecture (UISA)*, *virtual environment architecture (VEA)*, and *operating environment architecture (OEA)*; and the privilege level of the instruction—user- or supervisor-level (an instruction is assumed to be user-level unless the legend specifies that it is supervisor-level); and the instruction formats. The format diagrams show, horizontally, all valid combinations of instruction fields.

Note that the *architecture* specification refers to user-level and supervisor-level as problem state and privileged state, respectively.

## Instruction Formats

Instructions are four bytes long and *word*-aligned, so when instruction addresses are presented to the processor (as in branch instructions) the two low-order bits are ignored. Similarly, whenever the processor develops an instruction address, its two low-order bits are zero. Bits 0–5 always specify the *primary opcode*. Many instructions also have an *extended opcode*. The remaining bits of the instruction contain one or more fields for the different instruction formats.

Some instruction fields are reserved or must contain a predefined value as shown in the individual instruction layouts. If a *reserved field* does not have all bits *cleared*, or if a field that must contain a particular value does not contain that value, the instruction form is invalid.

## Split-Field Notation

Some instruction fields occupy more than one contiguous sequence of bits or occupy a contiguous sequence of bits used in permuted order. Such a field is called a split field. Split fields that represent the concatenation of the sequences from left to right are shown in lowercase letters. These split fields—*spr<sub>2</sub>* and *tbr*—are described in Table 1.

**Table 1. Split-Field Notation and Conventions**

Field	Description
spr (11–20)	This field is used to specify a special-purpose register for the <b>mtspr</b> and <b>mfspr</b> instructions.
tbr (11–20)	This field is used to specify either the time base lower (TBL) or time base upper (TBU).

Split fields that represent the concatenation of the sequences in some order, which need not be left to right (as described for each affected instruction) are shown in uppercase letters. These split fields—MB, ME, and SH—are described in Table 2.

## Instruction Fields

Table 2 describes the instruction fields used in the various instruction formats.

**Table 2. Instruction Syntax Conventions**

Field	Description
AA (30)	Absolute address bit. 0 The immediate field represents an address relative to the current instruction address (CIA). The effective (logical) address of the branch is either the sum of the LI field sign-extended to 32 bits and the address of the branch instruction or the sum of the BD field sign-extended to 32 bits and the address of the branch instruction. 1 The immediate field represents an absolute address. The effective address (EA) of the branch is the LI field sign-extended to 32 bits or the BD field sign-extended to 32 bits. <b>Note:</b> The LI and BD fields are sign-extended to 32.
BD (16–29)	Immediate field specifying a 14-bit signed two's complement branch displacement that is concatenated on the right with 0b00 and sign-extended to 32 bits.
BI (11–15)	This field is used to specify a bit in the CR to be used as the condition of a branch conditional instruction.
BO (6–10)	This field is used to specify options for the branch conditional instructions.
crbA (11–15)	This field is used to specify a bit in the CR to be used as a source.
crbB (16–20)	This field is used to specify a bit in the CR to be used as a source.
CRM (12–19)	This field mask is used to identify the CR fields that are to be updated by the <b>mtcrf</b> instruction.
d (16–31)	Immediate field specifying a 16-bit signed two's complement integer that is sign-extended to 32 bits.
frC (21–25)	NOT USED BY MPCxxx.
frD (6–10)	NOT USED BY MPCxxx.
frS (6–10)	NOT USED BY MPCxxx.
IMM (16–19)	NOT USED BY MPCxxx.
LI (6–29)	Immediate field specifying a 24-bit signed two's complement integer that is concatenated on the right with 0b00 and sign-extended to 32 bits.
LK (31)	Link bit. 0 Does not update the link register (LR). 1 Updates the LR. If the instruction is a branch instruction, the address of the instruction following the branch instruction is placed into the LR.
MB (21–25) and ME (26–30)	These fields are used in rotate instructions to specify a 32-bit mask.
NB (16–20)	This field is used to specify the number of bytes to move in an immediate string load or store.
OE (21)	This field is used for extended arithmetic to enable setting OV and SO in the XER.
OPCD (0–5)	Primary opcode field

**Table 2. Instruction Syntax Conventions (Continued)**

Field	Description
<i>rA</i> (11–15)	This field is used to specify a GPR to be used as a source or destination.
<i>rB</i> (16–20)	This field is used to specify a GPR to be used as a source.
<i>Rc</i> (31)	<i>Record bit.</i> 0 Does not update the condition register (CR). 1 Updates the CR to reflect the result of the operation. For integer instructions, CR bits 0–2 are <i>set</i> to reflect the result as a signed quantity and CR bit 3 receives a copy of the summary overflow bit, XER[SO]. The result as an unsigned quantity or a bit string can be deduced from the EQ bit. (Note that exceptions are referred to as interrupts in the architecture specification.)
<i>rD</i> (6–10)	This field is used to specify a GPR to be used as a destination.
<i>rS</i> (6–10)	This field is used to specify a GPR to be used as a source.
SH (16–20)	This field is used to specify a shift amount.
SIMM (16–31)	This immediate field is used to specify a 16-bit signed integer.
SR (12–15)	This field is used to specify one of the 16 segment registers.
TO (6–10)	This field is used to specify the conditions on which to trap.
UIMM (16–31)	This immediate field is used to specify a 16-bit unsigned integer.
XO (21–30, 22–30, 26–30)	Extended opcode field.

## Notation and Conventions

The operation of some instructions is described by a semiformal language (pseudocode). See Table 3 for a list of pseudocode notation and conventions used throughout this chapter.

**Table 3. Notation and Conventions**

Notation/Convention	Meaning
$\leftarrow$	Assignment
$\leftarrow_{\text{iea}}$	Assignment of an instruction effective address.
$\neg$	NOT logical operator
$*$	Multiplication
$\div$	Division (yielding quotient)
$+$	Two's-complement addition
$-$	Two's-complement subtraction, unary minus
$=, \neq$	Equals and Not Equals relations
$<, \leq, >, \geq$	Signed comparison relations
$.$ (period)	Update. When used as a character of an instruction mnemonic, a period (.) means that the instruction updates the condition register field.

**Table 3. Notation and Conventions (Continued)**

Notation/Convention	Meaning
c	Carry. When used as a character of an instruction mnemonic, a 'c' indicates a carry out in XER[CA].
e	Extended Precision. When used as the last character of an instruction mnemonic, an 'e' indicates the use of XER[CA] as an operand in the instruction and records a carry out in XER[CA].
o	Overflow. When used as a character of an instruction mnemonic, an 'o' indicates the record of an overflow in XER[OV] and CR0[SO] for integer instructions.
<U, >U	Unsigned comparison relations
?	Unordered comparison relation
&,	AND, OR logical operators
	Used to describe the concatenation of two values (that is, 010    111 is the same as 010111)
$\oplus$ , $\equiv$	Exclusive-OR, Equivalence logical operators (for example, $(a \equiv b) = (a \oplus \neg b)$ )
0bnnnn	A number expressed in binary format.
0xnnnn	A number expressed in hexadecimal format.
(n)x	The replication of x, n times (that is, x concatenated to itself n – 1 times). (n)0 and (n)1 are special cases. A description of the special cases follows: <ul style="list-style-type: none"> <li>• (n)0 means a field of n bits with each bit equal to 0. Thus (5)0 is equivalent to 0b00000.</li> <li>• (n)1 means a field of n bits with each bit equal to 1. Thus (5)1 is equivalent to 0b11111.</li> </ul>
(rA)[0]	The contents of rA if the rA field has the value 1–31, or the value 0 if the rA field is 0.
(rX)	The contents of rX
x[n]	n is a bit or field within x, where x is a register
$x^n$	x is raised to the nth power
ABS(x)	Absolute value of x
CEIL(x)	Least integer $\geq$ x
Characterization	Reference to the setting of status bits in a standard way that is explained in the text.
CIA	Current instruction address. The 32-bit address of the instruction being described by a sequence of pseudocode. Used by relative branches to set the next instruction address (NIA) and by branch instructions with LK = 1 to set the link register. Does not correspond to any architected register.
Clear	Clear the leftmost or rightmost n bits of a register to 0. This operation is used for rotate and shift instructions.
Clear left and shift left	Clear the leftmost b bits of a register, then shift the register left by n bits. This operation can be used to scale a known non-negative array index by the width of an element. These operations are used for rotate and shift instructions.
Cleared	Bits are set to 0.

**Table 3. Notation and Conventions (Continued)**

Notation/Convention	Meaning
Do	Do loop. <ul style="list-style-type: none"> <li>• Indenting shows range.</li> <li>• "To" and/or "by" clauses specify incrementing an iteration variable.</li> <li>• "While" clauses give termination conditions.</li> </ul>
Extract	Select a field of $n$ bits starting at bit position $b$ in the source register, right or left justify this field in the target register, and clear all other bits of the target register to zero. This operation is used for rotate and shift instructions.
EXTS( $x$ )	Result of extending $x$ on the left with sign bits
GPR( $x$ )	<i>General-purpose register <math>x</math></i>
if...then...else...	Conditional execution, indenting shows range, else is optional.
Insert	Select a field of $n$ bits in the source register, insert this field starting at bit position $b$ of the target register, and leave other bits of the target register unchanged. (No <i>simplified mnemonic</i> is provided for insertion of a field when operating on double words; such an insertion requires more than one instruction.) This operation is used for rotate and shift instructions. (Note that simplified mnemonics are referred to as extended mnemonics in the architecture specification.)
Leave	Leave innermost do loop, or the do loop described in leave statement.
MASK( $x, y$ )	Mask having ones in positions $x$ through $y$ (wrapping if $x > y$ ) and zeros elsewhere.
MEM( $x, y$ )	Contents of $y$ bytes of memory starting at address $x$ .
NIA	Next instruction address, which is the 32-bit address of the next instruction to be executed (the branch destination) after a successful branch. In pseudocode, a successful branch is indicated by assigning a value to NIA. For instructions which do not branch, the next instruction address is CIA + 4. Does not correspond to any architected register.
OEA	PowerPC operating environment architecture
Rotate	Rotate the contents of a register right or left $n$ bits without masking. This operation is used for rotate and shift instructions.
Set	Bits are set to 1.
Shift	Shift the contents of a register right or left $n$ bits, clearing vacated bits (logical shift). This operation is used for rotate and shift instructions.
SPR( $x$ )	Special-purpose register $x$
TRAP	Invoke the system trap handler.
Undefined	An undefined value. The value may vary from one implementation to another, and from one execution to another on the same implementation.
UISA	PowerPC user instruction set architecture
VEA	PowerPC virtual environment architecture

Table 4 describes instruction field notation conventions used throughout this document.

**Table 4. Instruction Field Conventions**

The Architecture Specification	Equivalent to:
BA, BB, BT	<b>crbA, crbB, crbD</b> (respectively)
D	d
DS	ds
FXM	CRM
RA, RB, RT, RS	rA, rB, rD, rS (respectively)
SI	SIMM
U	IMM
UI	UIMM
/, //, ///	0...0 (shaded)

Precedence rules for pseudocode operators are summarized in Table 5.

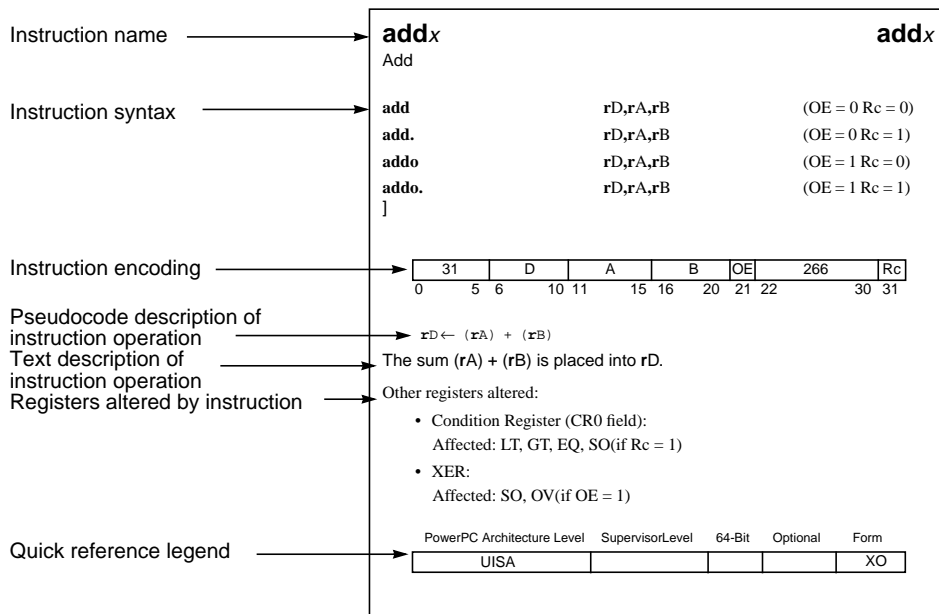

**Table 5. Precedence Rules**

Operators	Associativity
$x[n]$ , function evaluation	Left to right
$(n)x$ or replication, $x(n)$ or exponentiation	Right to left
unary $-$ , $\neg$	Right to left
$*$ , $\div$	Left to right
$+$ , $-$	Left to right
$\parallel$	Left to right
$=$ , $\neq$ , $<$ , $\leq$ , $>$ , $\geq$ , $<U$ , $>U$ , $?$	Left to right
$\&$ , $\oplus$ , $\equiv$	Left to right
$ $	Left to right
$-$ (range)	None
$\leftarrow$ , $\leftarrow_{iea}$	None

Operators higher in Table 5 are applied before those lower in the table. Operators at the same level in the table associate from left to right, from right to left, or not at all, as shown. For example, “ $-$ ” (unary minus) associates from left to right, so  $a - b - c = (a - b) - c$ . Parentheses are used to override the evaluation order implied by Table 5, or to increase clarity; parenthesized expressions are evaluated before serving as operands.

# MPCxxx Instruction Set

The remainder of this chapter lists and describes the instruction set for the MPCxxx. The instructions are listed in alphabetical order by mnemonic. Figure 1 shows the format for each instruction description page.

## Instruction Description

Note that the execution unit that executes the instruction may not be the same for all PowerPC processors.

# add<sub>x</sub>

Add

# add<sub>x</sub>

**add**                      **rD,rA,rB**    (OE = 0 Rc = 0)  
**add.**                    **rD,rA,rB**    (OE = 0 Rc = 1)  
**addo**                    **rD,rA,rB**    (OE = 1 Rc = 0)  
**addo.**                   **rD,rA,rB**    (OE = 1 Rc = 1)

$$rD \leftarrow (rA) + (rB)$$

The sum (rA) + (rB) is placed into rD.

The **add** instruction is preferred for addition because it sets few status bits.

Other registers altered:

- Condition Register (CR0 field):  
 Affected: LT, GT, EQ, SO                      (if Rc = 1)  
 Note: CR0 field may not reflect the “true” (infinitely precise) result if overflow occurs (see XER below).
- XER:  
 Affected: SO, OV                                      (if OE = 1)

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			XO

# addc<sub>x</sub>

Add Carrying

# addc<sub>x</sub>

<b>addc</b>	<b>rD,rA,rB</b>	(OE = 0 Rc = 0)
<b>addc.</b>	<b>rD,rA,rB</b>	(OE = 0 Rc = 1)
<b>addco</b>	<b>rD,rA,rB</b>	(OE = 1 Rc = 0)
<b>addco.</b>	<b>rD,rA,rB</b>	(OE = 1 Rc = 1)

$rD \leftarrow (rA) + (rB)$

The sum (rA) + (rB) is placed into rD.

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO (if Rc = 1)  
Note: CR0 field may not reflect the “true” (infinitely precise) result if overflow occurs (see XER below).
- XER:  
Affected: CA  
Affected: SO, OV (if OE = 1)

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			XO

# adde<sub>x</sub>

Add Extended

# adde<sub>x</sub>

**adde**                      **rD,rA,rB**    (OE = 0 Rc = 0)  
**adde.**                    **rD,rA,rB**    (OE = 0 Rc = 1)  
**addeo**                    **rD,rA,rB**    (OE = 1 Rc = 0)  
**addeo.**                   **rD,rA,rB**    (OE = 1 Rc = 1)

$$rD \leftarrow (rA) + (rB) + XER[CA]$$

The sum (rA) + (rB) + XER[CA] is placed into rD.

Other registers altered:

- Condition Register (CR0 field):  
 Affected: LT, GT, EQ, SO                      (if Rc = 1)  
 Note: CR0 field may not reflect the “true” (infinitely precise) result if overflow occurs (see XER below).
- XER:  
 Affected: CA  
 Affected: SO, OV                                      (if OE = 1)

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			XO

# addi

Add Immediate

# addi

**addi**                      rD,rA,SIMM

```
if rA = 0 then rD ← EXTS(SIMM)
else rD ← rA + EXTS(SIMM)
```

The sum (rA|0) + SIMM is placed into rD.

The **addi** instruction is preferred for addition because it sets few status bits. Note that **addi** uses the value 0, not the contents of GPR0, if rA = 0.

Other registers altered:

- None

Simplified mnemonics:

<b>li</b>	rD,value	equivalent to	<b>addi</b>	rD,0,value
<b>la</b>	rD,disp(rA)	equivalent to	<b>addi</b>	rD,rA,disp
<b>subi</b>	rD,rA,value	equivalent to	<b>addi</b>	rD,rA,-value

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			D

# addic

addic

Add Immediate Carrying

**addic**                    **rD,rA,SIMM**

$$rD \leftarrow (rA) + EXTS(SIMM)$$

The sum (rA) + SIMM is placed into rD.

Other registers altered:

- XER:  
    Affected: CA

Simplified mnemonics:

**subic** rD,rA,value                    equivalent to                    **addic** rD,rA,-value

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			D

# addic.

# addic.

Add Immediate Carrying and Record

**addic.**                      **rD,rA,SIMM**

$$rD \leftarrow (rA) + EXTS(SIMM)$$

The sum (rA) + SIMM is placed into rD.

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO  
**Note:** CR0 field may not reflect the “true” (infinitely precise) result if overflow occurs (see XER below).
- XER:  
Affected: CA

Simplified mnemonics:

**subic.rD,rA,value**                      equivalent to                      **addic.rD,rA,-value**

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			D

# addis

Add Immediate Shifted

# addis

**addis**                      rD,rA,SIMM

```
if rA = 0 then rD ← EXTS(SIMM || (16)0)
else    rD ← (rA) + EXTS(SIMM || (16)0)
```

The sum (rA|0) + (SIMM || 0x0000) is placed into rD.

The **addis** instruction is preferred for addition because it sets few status bits. Note that **addis** uses the value 0, not the contents of GPR0, if rA = 0.

Other registers altered:

- None

Simplified mnemonics:

<b>lis</b> rD,value	equivalent to	<b>addis</b> rD,0,value
<b>subis</b> rD,rA,value	equivalent to	<b>addis</b> rD,rA,-value

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			D

# addmex

Add to Minus One Extended

# addmex

<b>addme</b>	<b>rD,rA</b>	(OE = 0 Rc = 0)
<b>addme.</b>	<b>rD,rA</b>	(OE = 0 Rc = 1)
<b>addmeo</b>	<b>rD,rA</b>	(OE = 1 Rc = 0)
<b>addmeo.</b>	<b>rD,rA</b>	(OE = 1 Rc = 1)

 Reserved

$$rD \leftarrow (rA) + XER[CA] - 1$$

The sum  $(rA) + XER[CA] + 0xFFFF\_FFFF\_FFFF\_FFFF$  is placed into rD.

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO (if Rc = 1)  
**Note:** CR0 field may not reflect the “true” (infinitely precise) result if overflow occurs (see XER below).
- XER:  
Affected: CA  
Affected: SO, OV (if OE = 1)

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			XO

# addze<sub>x</sub>

Add to Zero Extended

# addze<sub>x</sub>

<b>addze</b>	<b>rD,rA</b>	(OE = 0 Rc = 0)
<b>addze.</b>	<b>rD,rA</b>	(OE = 0 Rc = 1)
<b>addzeo</b>	<b>rD,rA</b>	(OE = 1 Rc = 0)
<b>addzeo.</b>	<b>rD,rA</b>	(OE = 1 Rc = 1)

☐ Reserved

$$rD \leftarrow (rA) + XER[CA]$$

The sum  $(rA) + XER[CA]$  is placed into rD.

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO (if Rc = 1)  
**Note:** CR0 field may not reflect the “true” (infinitely precise) result if overflow occurs (see XER below).
- XER:  
Affected: CA  
Affected: SO, OV (if OE = 1)

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			XO

# and<sub>x</sub>

AND

# and<sub>x</sub>

**and**  $rA, rS, rB$  (Rc = 0)

**and.**  $rA, rS, rB$  (Rc = 1)

$$rA \leftarrow (rS) \& (rB)$$

The contents of **rS** are ANDed with the contents of **rB** and the result is placed into **rA**.

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO (if Rc = 1)

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			X

# andc<sub>x</sub>

AND with Complement

# andc<sub>x</sub>

**andc**                                      **rA,rS,rB**                                      (**Rc = 0**)

**andc.**                                      **rA,rS,rB**                                      (**Rc = 1**)

$$rA \leftarrow (rS) + \neg (rB)$$

The contents of **rS** are ANDed with the one's complement of the contents of **rB** and the result is placed into **rA**.

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO                                      (if **Rc = 1**)

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			X

# andi.

AND Immediate

# andi.

**andi.**                      **rA,rS,UIMM**

$$rA \leftarrow (rS) \& ((\underline{16})0 \parallel UIMM)$$

The contents of **rS** are ANDed with 0x0000 || UIMM and the result is placed into **rA**.

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			D

# andis.

AND Immediate Shifted

# andis.

**andis.**                      **rA,rS,UIMM**

$$rA \leftarrow (rS) + (UIMM \mid \mid (16)0)$$

The contents of **rS** are ANDed with UIMM || 0x0000 and the result is placed into **rA**.

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			D

# **b<sub>x</sub>** Branch

**b<sub>x</sub>**

<b>b</b>	target_addr	(AA = 0 LK = 0)
<b>ba</b>	target_addr	(AA = 1 LK = 0)
<b>bl</b>	target_addr	(AA = 0 LK = 1)
<b>bla</b>	target_addr	(AA = 1 LK = 1)

18	LI	AA	LK
0	5 6	29 30	31

```

if AA then NIA ← iea EXTS(LI || 0b00)
else NIA ← iea CIA + EXTS(LI || 0b00)
if LK then LR ← iea CIA + 4

```

target\_addr specifies the branch target address.

If AA = 0, then the branch target address is the sum of LI || 0b00 sign-extended and the address of this instruction. If AA = 1, then the branch target address is the value LI || 0b00 sign-extended. If LK = 1, then the effective address of the instruction following the branch instruction is placed into the link register.

Other registers altered:

Affected: Link Register (LR) (if LK = 1)

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			I

<b>bc</b>	BO, BI, target_addr	(AA = 0 LK = 0)
<b>bca</b>	BO, BI, target_addr	(AA = 1 LK = 0)
<b>bcl</b>	BO, BI, target_addr	(AA = 0 LK = 1)
<b>bcla</b>	BO, BI, target_addr	(AA = 1 LK = 1)

16	BO	BI	BD	AA	LK
0	5 6	10 11	15 16	29 30	31

```

m ← 32
if ¬ BO[2] then CTR ← CTR - 1
ctr_ok ← BO[2] | (BO[3])
cond_ok ← BO[0] | (CR[BI] ≡ BO[1])
if ctr_ok & cond_ok then
  if AA then NIA ←iea EXTS(BD || 0b00)
  else NIA ←iea CIA + EXTS(BD || 0b00)
  if LK then LR ←iea CIA + 4

```

The BI field specifies the bit in the condition register (CR) to be used as the condition of the branch. The BO field is encoded as described in Table 6.

**Table 6. BO Operand Encodings**

BO	Description
0000y	Decrement the count register (CTR), then branch if the condition is FALSE.
0001y	Decrement the CTR, then branch if the condition is FALSE.
001zy	Branch if the condition is FALSE.
0100y	Decrement the CTR, then branch if the condition is TRUE.
0101y	Decrement the CTR, then branch if the condition is TRUE.
011zy	Branch if the condition is TRUE.
1z00y	Decrement the CTR, then branch if the decremented CTR ≠ 0.
1z01y	Decrement the CTR, then branch if the decremented CTR = 0.
1z1zz	Branch always.

In this table, z indicates a bit that is ignored.

Note that the z bits should be cleared, as they may be assigned a meaning in some future version of the MPCxxx.

The y bit provides a hint about whether a conditional branch is likely to be taken.

target\_addr specifies the branch target address.

If AA = 0, the branch target address is the sum of BD || 0b00 sign-extended and the address of this instruction. If AA = 1, the branch target address is the value BD || 0b00 sign-extended. If LK = 1, the effective address of the instruction following the branch instruction is placed into the link register.

Other registers altered:

Affected: Count Register (CTR) (if BO[2] = 0)

Affected: Link Register (LR) (if LK = 1)

Simplified mnemonics:

<b>blt</b>	target	equivalent to	<b>bc</b>	<b>12,0,target</b>
<b>bne</b>	<b>cr2,target</b>	equivalent to	<b>bc</b>	<b>4,10,target</b>
<b>bdnz</b>	target	equivalent to	<b>bc</b>	<b>16,0,target</b>

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			B

**bcctr** BO, BI (LK = 0)

**bcctrl** BO, BI (LK = 1)

 Reserved

19	BO	BI	0000 0	528	LK
0	5 6	10 11	15 16	20 21	30 31

```

cond_ok ← BO[0] | (CR[BI] ≡ BO[1])
if cond_ok then
    NIA ←iea CTR || 0b00
    if LK then LR ←iea CIA + 4

```

The BI field specifies the bit in the condition register to be used as the condition of the branch. The BO field is encoded as described in Table 7.

**Table 7. BO Operand Encodings**

BO	Description
0000y	Decrement the count register (CTR), then branch if the condition is FALSE.
0001y	Decrement the CTR, then branch if the condition is FALSE.
001zy	Branch if the condition is FALSE.
0100y	Decrement the CTR, then branch if the condition is TRUE.
0101y	Decrement the CTR, then branch if the condition is TRUE.
011zy	Branch if the condition is TRUE.
1z00y	Decrement the CTR, then branch if the decremented CTR ≠ 0.
1z01y	Decrement the CTR, then branch if the decremented CTR = 0.
1z1zz	Branch always.

In this table, z indicates a bit that is ignored.

Note that the z bits should be cleared, as they may be assigned a meaning in some future version of the MPCxxx.

The y bit provides a hint about whether a conditional branch is likely to be taken.

The branch target address is CTR || 0b00.

If LK = 1, the effective address of the instruction following the branch instruction is placed into the link register.

If the “decrement and test CTR” option is specified (BO[2] = 0), the instruction form is invalid.

Other registers altered:

Affected: Link Register (LR) (if LK = 1)

# dcbf

Data Cache Block Flush

# dcbf

**dcbf**

**rA,rB**

EA is the sum  $(rA|0) + (rB)$ .

The **dcbf** instruction invalidates the *block* in the data *cache* addressed by EA, copying the block to memory first, if there is any dirty data in it. If the processor is a multiprocessor implementation and the block is marked coherency-required, the processor will, if necessary, send an address-only broadcast to other processors. The broadcast of the **dcbf** instruction causes another processor to copy the block to memory, if it has dirty data, and then invalidate the block from the cache.

The action taken depends on the memory mode associated with the block containing the byte addressed by EA and on the state of that block. The list below describes the action taken for the various states of the *memory coherency* attribute (M bit).

- Coherency required
  - Unmodified block—Invalidates copies of the block in the data caches of all processors.
  - Modified block—Copies the block to memory. Invalidates copies of the block in the data caches of all processors.
  - Absent block—If modified copies of the block are in the data caches of other processors, causes them to be copied to memory and invalidated in those data caches. If unmodified copies are in the data caches of other processors, causes those copies to be invalidated in those data caches.
- Coherency not required
  - Unmodified block—Invalidates the block in the processor's data cache.
  - Modified block—Copies the block to memory. Invalidates the block in the processor's data cache.
  - Absent block (target block not in cache)—No action is taken.

The function of this instruction is independent of the write-through, *write-back* and *caching-inhibited*/allowed modes of the block containing the byte addressed by EA.

This instruction may be treated as a load from the addressed byte with respect to address translation and memory protection. It may also be treated as a load for referenced and changed bit recording except that referenced and changed bit recording may not occur.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
VEA			X

# dcbi

Data Cache Block Invalidate

# dcbi

dcbi

rA,rB

 Reserved

EA is the sum  $(rA|0) + (rB)$ .

The action taken is dependent on the memory mode associated with the block containing the byte addressed by EA and on the state of that block. The list below describes the action taken if the block containing the byte addressed by EA is or is not in the cache.

- Coherency required
  - Unmodified block—Invalidates copies of the block in the data caches of all processors.
  - Modified block—Invalidates copies of the block in the data caches of all processors. (Discards the modified contents.)
  - Absent block—If copies of the block are in the data caches of any other processor, causes the copies to be invalidated in those data caches. (Discards any modified contents.)
- Coherency not required
  - Unmodified block—Invalidates the block in the processor's data cache.
  - Modified block—Invalidates the block in the processor's data cache. (Discards the modified contents.)
  - Absent block (target block not in cache)—No action is taken.

When data address translation is enabled,  $MSR[DR] = 1$ , and the *virtual address* has no translation, a DSI *exception* occurs. The function of this instruction is independent of the *write-through* and caching-inhibited/allowed modes of the block containing the byte addressed by EA. This instruction operates as a store to the addressed byte with respect to address translation and protection. The *referenced* and *changed bits* are modified appropriately. This is a supervisor-level instruction.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
OEA	√		X

# dcbst

Data Cache Block Store

# dcbst

**dcbst**

**rA,rB**

☐ Reserved

EA is the sum  $(rA|0) + (rB)$ .

The **dcbst** instruction executes as follows:

- If the block containing the byte addressed by EA is in coherency-required mode, and a block containing the byte addressed by EA is in the data cache of any processor and has been modified, the writing of it to main memory is initiated.
- If the block containing the byte addressed by EA is in coherency-not-required mode, and a block containing the byte addressed by EA is in the data cache of this processor and has been modified, the writing of it to main memory is initiated.

The function of this instruction is independent of the write-through and caching-inhibited/allowed modes of the block containing the byte addressed by EA. The processor treats this instruction as a load from the addressed byte with respect to address translation and memory protection. It may also be treated as a load for referenced and changed bit recording except that referenced and changed bit recording may not occur.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
VEA			X

dcbt

dcbt

Data Cache Block Touch

dcbtrA,rB

EA is the sum (rA|0) + (rB).

This instruction is a hint that performance will probably be improved if the block containing the byte addressed by EA is *fetch*ed into the data cache, because the program will probably soon load from the addressed byte. The hint is ignored if the block is caching-inhibited. Executing **dcbt** does not cause the system alignment error handler to be invoked.

This instruction may be treated as a load from the addressed byte with respect to address translation, memory protection, and reference and change recording, except that no exception occurs in the case of a translation fault or protection violation.

The program uses the **dcbt** instruction to request a *cache block* fetch before it is actually needed by the program. The program can later execute load instructions to put data into registers. However, the processor is not obliged to load the addressed block into the data cache.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
VEA			X

# dcbtst

Data Cache Block Touch for Store

# dcbtst

**dcbtst**  $rA, rB$

EA is the sum  $(rA|0) + (rB)$ .

This instruction is a hint that performance will be improved if the block containing the byte addressed by EA is fetched into the data cache, because the program will probably soon store into the addressed byte. The hint is ignored if the block is caching-inhibited. Executing **dcbtst** does not cause the system alignment error handler to be invoked.

This instruction operates as a load from the addressed byte with respect to address translation and protection, except that no exception occurs in the case of a translation fault or protection violation. Also, if the referenced and changed bits are recorded, they are recorded as if the access was a load.

The program uses **dcbtst** to request a cache block fetch to guarantee that a subsequent store will be to a cached location. The program can later execute store instructions to put data into memory. However, the processor is not obliged to load the addressed cache block into the data cache.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
VEA			X

# dcbz

Data Cache Block Set to Zero

# dcbz

**dcbz**

**rA,rB**

EA is the sum  $(rA|0) + (rB)$ .

The **dcbz** instruction executes as follows:

- If the cache block containing the byte addressed by EA is in the data cache, all bytes are cleared.
- If the cache block containing the byte addressed by EA is not in the data cache and the corresponding *page* is caching-allowed, the cache block is allocated in the data cache (without fetching the block from main memory), and all bytes are cleared.
- If the page containing the byte addressed by EA is in caching-inhibited or write-through mode, either all bytes of main memory that correspond to the addressed cache block are cleared or the alignment *exception handler* is invoked. The exception handler clears all bytes in main memory that corresponds to the addressed cache block.
- If the cache block containing the byte addressed by EA is in coherency-required mode, and the cache block exists in the data cache(s) of any other processor(s), it is kept coherent in those caches.

This instruction is treated as a store to the addressed byte with respect to address translation, memory protection, referenced and changed recording and the ordering enforced by **eieio** or by the combination of caching-inhibited and guarded attributes for a page.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form

# divw<sub>x</sub>

Divide Word

# divw<sub>x</sub>

<b>divw</b>	<b>rD,rA,rB</b>	(OE = 0 Rc = 0)
<b>divw.</b>	<b>rD,rA,rB</b>	(OE = 0 Rc = 1)
<b>divwo</b>	<b>rD,rA,rB</b>	(OE = 1 Rc = 0)
<b>divwo.</b>	<b>rD,rA,rB</b>	(OE = 1 Rc = 1)

```

dividend ← (rA)
divisor ← (rB)
rD ← dividend ÷ divisor

```

The dividend is the contents of **rA**. The divisor is the contents of **rB**. The 32-bit quotient is formed and placed in rD. The remainder is not supplied as a result.

Both the operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies the equation—dividend = (quotient \* divisor) + r where  $0 \leq r < |\text{divisor}|$  (if the dividend is non-negative), and  $-|\text{divisor}| < r \leq 0$  (if the dividend is negative).

If an attempt is made to perform any of the divisions— $0x8000\_0000 \div -1$  or  $\langle \text{anything} \rangle \div 0$ —then the contents of **rD** are undefined, as are the contents of the LT, GT, and EQ bits of the CR0 field (if Rc = 1). In this case, if OE = 1 then OV is set.

The 32-bit signed remainder of dividing the contents of **rA** by the contents of **rB** can be computed as follows, except in the case that the contents of **rA** = -231 and the contents of **rB** = -1.

<b>divw</b>	<b>rD,rA,rB</b>	# rD = quotient
<b>mullw</b>	<b>rD,rD,rB</b>	# rD = quotient * divisor
<b>subf</b>	<b>rD,rD,rA</b>	# rD = remainder

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO (if Rc = 1)
- XER:  
Affected: SO, OV (if OE = 1)

**Note:** The setting of the affected bits in the XER is mode-independent, and reflects overflow of the 32-bit result.

PowerPC Architecture Level	Supervisor Level	Optional	Form
UI5A			XO

# divwu<sub>x</sub>

Divide Word Unsigned

# divwu<sub>x</sub>

<b>divwu</b>	<b>rD,rA,rB</b>	(OE = 0 Rc = 0)
<b>divwu.</b>	<b>rD,rA,rB</b>	(OE = 0 Rc = 1)
<b>divwuo</b>	<b>rD,rA,rB</b>	(OE = 1 Rc = 0)
<b>divwuo.</b>	<b>rD,rA,rB</b>	(OE = 1 Rc = 1)

```
dividend ← (rA)
divisor ← (rB)
rD ← dividend ÷ divisor
```

The dividend is the contents of **rA**. The divisor is the contents of **rB**. A 32-bit quotient is formed. The 32-bit quotient is placed into **rD**. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as unsigned integers, except that if **Rc** = 1 the first three bits of **CR0** field are set by signed comparison of the result to zero. The quotient is the unique unsigned integer that satisfies the equation—dividend = (quotient \* divisor) + *r* (where  $0 \leq r < \text{divisor}$ ). If an attempt is made to perform the division—<anything> ÷ 0—then the contents of **rD** are undefined as are the contents of the **LT**, **GT**, and **EQ** bits of the **CR0** field (if **Rc** = 1). In this case, if **OE** = 1 then **OV** is set.

The 32-bit unsigned remainder of dividing the contents of **rA** by the contents of **rB** can be computed as follows:

<b>divwu</b>	<b>rD,rA,rB</b>	# <b>rD</b> = quotient
<b>mullw</b>	<b>rD,rD,rB</b>	# <b>rD</b> = quotient * divisor
<b>subf</b>	<b>rD,rD,rA</b>	# <b>rD</b> = remainder

Other registers altered:

- Condition Register (CR0 field):

Affected: LT, GT, EQ, SO (if Rc = 1)

- XER:

Affected: SO, OV (if OE = 1)

**Note:** The setting of the affected bits in the XER is mode-independent, and reflects overflow of the 32-bit result.

UI5A			XO

## External Control In Word Indexed

**eciwx**

 $r_D, r_A, r_B$ 

The **eciwx** instruction allows the system designer to map special devices in an alternative way. The MMU translation of the EA is not used to select the special device, as it is used in most instructions such as loads and stores. Rather, it is used as an address operand that is passed to the device over the address bus. Four other pins (the burst and size pins on the 60x bus) are used to select the device; these four pins output the 4-bit resource ID (RID) field that is located in the EAR register. The **eciwx** instruction also loads a word from the data bus that is output by the special device.

The **eciwx** instruction and the EAR register can be very efficient when mapping special devices such as graphics devices that use addresses as pointers.

```

if rA = 0 then b ← 0
else b ← (rA)
EA ← b + (rB)
paddr ← address translation of EA
send load word request for paddr to device identified by EAR[RID]
rD ← word from device

```

EA is the sum  $(r_A|0) + (r_B)$ .

A load word request for the physical address (referred to as real address in the architecture specification) corresponding to EA is sent to the device identified by EAR[RID], bypassing the cache. The word returned by the device is placed in rD. EAR[E] must be 1. If it is not, a DSI exception is generated.

EA must be a multiple of four. If it is not, one of the following occurs:

- A system alignment exception is generated.
- A DSI exception is generated (possible only if  $\text{EAR}[E] = 0$ ).
- The results are *boundedly undefined*.

The **eciwx** instruction is supported for EAs that reference memory *segments* in which  $SR[T] = 1$  and for EAs mapped by the DBAT registers. If the EA references a *direct-store* segment ( $SR[T] = 1$ ), either a DSI exception occurs or the results are boundedly undefined. However, note that the direct-store facility is being phased out of the architecture and will not likely be supported in future devices. Thus, software should not depend on its effects.

If this instruction is executed when MSR[DR] = 0 (real addressing mode), the results are boundedly undefined. This instruction is treated as a load from the addressed byte with respect to address translation, memory protection, referenced and changed bit recording, and the ordering performed by **eieio**. This instruction is optional in the PowerPC architecture.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form

ecowx

rS,rA,rB

☐ Reserved

The **ecowx** instruction and the EAR register can be very efficient when mapping special devices such as graphics devices that use addresses as pointers.

```

if rA = 0 then b ← 0
else b ← (rA)
EA ← b + (rB)
paddr ← address translation of EA
send store word request for paddr to device identified by EAR[RID]
send rS to device

```

EA is the sum  $(rA|0) + (rB)$ . A store word request for the physical address corresponding to EA and the contents of rS are sent to the device identified by EAR[RID], bypassing the cache. EAR[E] must be 1, if it is not, a DSI exception is generated. EA must be a multiple of four. If it is not, one of the following occurs:

- A system alignment exception is generated.
- A DSI exception is generated (possible only if EAR[E] = 0).
- The results are boundedly undefined.

The **ecowx** instruction is supported for effective addresses that reference memory segments in which  $SR[T] = 0$ , and for EAs mapped by the DBAT registers. If the EA references a direct-store segment ( $SR[T] = 1$ ), either a DSI exception occurs or the results are boundedly undefined. However, note that the direct-store facility is being phased out of the architecture and will not likely be supported in future devices. Thus, software should not depend on its effects.

If this instruction is executed when  $MSR[DR] = 0$  (real addressing mode), the results are boundedly undefined. This instruction is treated as a store from the addressed byte with respect to address translation, memory protection, nd referenced and changed bit recording, and the ordering performed by **ei**io. This instruction is optional in the PowerPC architecture.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
VEA		√	X

The **eieio** instruction provides an ordering function for the effects of load and store instructions executed by a processor. These loads and stores are divided into two sets, which are ordered separately. The *memory accesses* caused by a **dcbz** instruction are ordered like a store. The two sets follow:

1. Loads and stores to memory that is both caching-inhibited and guarded, and stores to memory that is write-through required.

The **eieio** instruction controls the order in which the accesses are performed in main memory. It ensures that all applicable memory accesses caused by instructions preceding the **eieio** instruction have completed with respect to main memory before any applicable memory accesses caused by instructions following the **eieio** instruction access main memory. It acts like a barrier that flows through the memory queues and to main memory, preventing the reordering of memory accesses across the barrier. No ordering is performed for **dcbz** if the instruction causes the system alignment error handler to be invoked.

All accesses in this set are ordered as a single set—that is, there is not one order for loads and stores to caching-inhibited and guarded memory and another order for stores to write-through required memory.

2. Stores to memory that have all of the following attributes—caching-allowed, write-through not required, and memory-coherency required.

The **eieio** instruction controls the order in which the accesses are performed with respect to coherent memory. It ensures that all applicable stores caused by instructions preceding the **eieio** instruction have completed with respect to coherent memory before any applicable stores caused by instructions following the **eieio** instruction complete with respect to coherent memory.

With the exception of **dcbz**, **eieio** does not affect the order of cache operations (whether caused explicitly by execution of a cache management instruction, or implicitly by the *cache coherency* mechanism). The **eieio** instruction does not affect the order of accesses in one set with respect to accesses in the other set.

The **eieio** instruction may complete before memory accesses caused by instructions preceding the **eieio** instruction have been performed with respect to main memory or coherent memory as appropriate.

The **eieio** instruction is intended for use in managing shared data structures, in accessing memory-mapped I/O, and in preventing load/store combining operations in main memory. For the first use, the shared data structure and the lock that protects it must be altered only by stores that are in the same set (1 or 2; see previous discussion). For the second use, **eieio** can be thought of as placing a barrier into the stream of memory accesses

issued by a processor, such that any given memory access appears to be on the same side of the barrier to both the processor and the I/O device.

Because the processor performs store operations in order to memory that is designated as both caching-inhibited and guarded, the **eieio** instruction is needed for such memory only when loads must be ordered with respect to stores or with respect to other loads.

Note that the **eieio** instruction does not connect hardware considerations to it such as multiprocessor implementations that send an **eieio** address-only broadcast (useful in some designs). For example, if a design has an external buffer that re-orders loads and stores for better bus efficiency, the **eieio** broadcast signals to that buffer that previous loads/stores (marked caching-inhibited, guarded, or write-through required) must complete before any following loads/stores (marked caching-inhibited, guarded, or write-through required).

# icbi

Instruction Cache Block Invalidate

# icbi

**icbi**

**rA,rB**

☐ Reserved

EA is the sum  $(rA|0) + (rB)$ .

If the block containing the byte addressed by EA is in coherency-required mode, and a block containing the byte addressed by EA is in the instruction cache of any processor, the block is made invalid in all such instruction caches, so that subsequent references cause the block to be refetched.

If the block containing the byte addressed by EA is in coherency-not-required mode, and a block containing the byte addressed by EA is in the instruction cache of this processor, the block is made invalid in that instruction cache, so that subsequent references cause the block to be refetched. The function of this instruction is independent of the write-through, write-back, and caching-inhibited/allowed modes of the block containing the byte addressed by EA.

This instruction is treated as a load from the addressed byte with respect to address translation and memory protection. It may also be treated as a load for referenced and changed bit recording except that referenced and changed bit recording may not occur. Implementations with a combined data and instruction cache treat the **icbi** instruction as a no-op, except that they may invalidate the target block in the instruction caches of other processors if the block is in coherency-required mode.

The **icbi** instruction invalidates the block at EA  $(rA|0 + rB)$ . If the processor is a multiprocessor implementation and the block is marked coherency-required, the processor will send an address-only broadcast to other processors causing those processors to invalidate the block from their instruction caches.

For faster processing, many implementations will not compare the entire EA  $(rA|0 + rB)$  with the tag in the instruction cache. Instead, they will use the bits in the EA to locate the set that the block is in, and invalidate all blocks in that set.

PowerPC Architecture Level	Supervisor Level	Optional	Form
VEA			X

# isync

Instruction Synchronize

# isync

## isync

The **isync** instruction provides an ordering function for the effects of all instructions executed by a processor. Executing an **isync** instruction ensures that all instructions preceding the the **isync** instruction have completed before the **isync** instruction completes, except that memory accesses caused by those instructions need not have been performed with respect to other processors and mechanisms. It also ensures that no subsequent instructions are initiated by the processor until after the **isync** instruction completes. Finally, it causes the processor to discard any prefetched instructions, with the effect that subsequent instructions will be fetched and executed in the context established by the instructions preceding the isync instruction. The **isync** instruction has no effect on the other processors or on their caches. This instruction is context synchronizing.

*Context synchronization* is necessary after certain code sequences that perform complex operations within the processor. These code sequences are usually operating system tasks that involve memory management. For example, if an instruction “A” changes the memory translation rules in the *memory management unit (MMU)*, the **isync** instruction should be executed so that the instructions following instruction “A” will be discarded from the pipeline and refetched according to the new translation rules. This instruction is context synchronizing.

Imw

Load Multiple Word

ImwrD,d(rA)

```
if rA = 0 then b ← 0
else b ← (rA)
EA ← b + EXTS(d)
r ← rD
do while r ≤ 31
  GPR(r) ← MEM(EA, 4)
  r ← r + 1
  EA ← EA + 4
```

EA is the sum (rA|0) + d.  $n = (32 - rD)$ .  $n$  consecutive words starting at EA are loaded into GPRs rD through r31.

EA must be a multiple of four. If it is not, either the system alignment exception handler is invoked or the results are boundedly undefined. If rA is in the range of registers specified to be loaded, including the case in which rA = 0, the instruction form is invalid.

Note that, in some implementations, this instruction is likely to have a greater latency and take longer to execute, perhaps much longer, than a sequence of individual load or store instructions that produce the same results.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			D

# lswi

Load String Word Immediate

# lswi

**lswi** **rD,rA,NB**

```

if rA = 0 then EA ← 0
else EA ← (rA)
if NB = 0 then n ← 32
elsen ← NB
r ← rD - 1
i ← 32
do while n > 0
    if i = 32 then
        r ← r + 1 (mod 32)
        GPR(r) ← 0
    GPR(r)[i-i + 7] ← MEM(EA, 1)
    i ← i + 8
    if i = 32 then i ← 0
    EA ← EA + 1
    n ← n - 1

```

EA is (rA|0). Let  $n = \text{NB}$  if  $\text{NB} \neq 0$ ,  $n = 32$  if  $\text{NB} = 0$ ;  $n$  is the number of bytes to load. Let  $nr = \text{CEIL}(n \div 4)$ ;  $nr$  is the number of registers to be loaded with data.

$n$  consecutive bytes starting at EA are loaded into GPRs rD through  $rD + nr - 1$ . Bytes are loaded left to right in each register. The sequence of registers wraps around to **r0** if required. If the 4 bytes of register  $rD + nr - 1$  are only partially filled, the unfilled low-order byte(s) of that register are cleared.

If rA is in the range of registers specified to be loaded, including the case in which  $rA = 0$ , the instruction form is invalid. Under certain conditions (for example, segment boundary crossing) the data alignment exception handler may be invoked.

Note that, in some implementations, this instruction is likely to have greater latency and take longer to execute, perhaps much longer, than a sequence of individual load or store instructions that produce the same results.

Other registers altered:

# lswx

Load String Word Indexed

# lswx

**lswx** **rD,rA,rB**

```

if rA = 0 then b ← 0
else b ← (rA)
EA ← b + (rB)
n ← XER[25–31]
r ← rD – 1
i ← 32
rD ← undefined
do while n > 0
  if i = 32 then
    r ← r + 1 (mod 32)
    GPR(r) ← 0
    GPR(r)[i–i + 7] ← MEM(EA, 1)
    i ← i + 8
  if i = 32 then i ← 0
  EA ← EA + 1
  n ← n – 1
  
```

EA is the sum (rA|0) + (rB). Let  $n = \text{XER}[25–31]$ ;  $n$  is the number of bytes to load. Let  $nr = \text{CEIL}(n \div 4)$ ;  $nr$  is the number of registers to receive data. If  $n > 0$ ,  $n$  consecutive bytes starting at EA are loaded into GPRs rD through rD + nr – 1.

Bytes are loaded left to right in each register. The sequence of registers wraps around through r0 if required. If the four bytes of rD + nr – 1 are only partially filled, the unfilled low-order byte(s) of that register are cleared. If  $n = 0$ , the contents of rD are undefined.

If rA or rB is in the range of registers specified to be loaded, including the case in which rA = 0, either the system illegal instruction error handler is invoked or the results are boundedly undefined. If rD = rA or rD = rB, the instruction form is invalid. If rD and rA both specify GPR0, the form is invalid.

Under certain conditions (for example, segment boundary crossing) the data alignment exception handler may be invoked. Note that, in some implementations, this instruction is likely to have a greater latency and take longer to execute, perhaps much longer, than a sequence of individual load or store instructions that produce the same results.

# lwarx

Load Word and Reserve Indexed

# lwarx

**lwarx** **rD,rA,rB**

☐ Reserved

```

if rA = 0 then b ← 0
else b ← (rA)
EA ← b + (rB)
RESERVE ← 1
RESERVE_ADDR ← physical_addr(EA)
rD ← MEM(EA, 4)
    
```

EA is the sum  $(rA|0) + (rB)$ . The word in memory addressed by EA is loaded into rD.

This instruction creates a reservation for use by a store word conditional indexed (**stwcx.**)instruction. The physical address computed from EA is associated with the reservation, and replaces any address previously associated with the reservation. EA must be a multiple of four. If it is not, either the system alignment exception handler is invoked or the results are boundedly undefined.

When the RESERVE bit is set, the processor enables hardware snooping for the block of memory addressed by the RESERVE address. If the processor detects that another processor writes to the block of memory it has reserved, it clears the RESERVE bit. The **stwcx.** instruction will only do a store if the RESERVE bit is set. The **stwcx.** instruction sets the CR0[EQ] bit if the store was successful and clears it if it failed. The **lwarx** and **stwcx.** combination can be used for atomic read-modify-write sequences. Note that the atomic sequence is not guaranteed, but its failure can be detected if CR0[EQ] = 0 after the **stwcx.** instruction.

# mf spr

Move from Special-Purpose Register

# mf spr

mf spr

rD, SPR

 Reserved

**\*Note:** This is a split field.

$$n \leftarrow \text{spr}[5-9] \parallel \text{spr}[0-4]$$

$$\text{rD} \leftarrow \text{SPR}(n)$$

In the PowerPC UISA, the SPR field denotes a special-purpose register, encoded as shown in Table 9. The contents of the designated special-purpose register are placed into rD.

**Table 9. PowerPC UISA SPR Encodings for mf spr**

SPR**			Register Name
Decimal	spr[5–9]	spr[0–4]	
1	00000	00001	XER
8	00000	01000	LR
9	00000	01001	CTR

\*\* Note that the order of the two 5-bit halves of the SPR number is reversed compared with the actual instruction coding.

If the SPR field contains any value other than one of the values shown in Table 9 (and the processor is in *user mode*), one of the following occurs:

- The system illegal instruction error handler is invoked.
- The system supervisor-level instruction error handler is invoked.
- The results are boundedly undefined.

Other registers altered:

- None

Simplified mnemonics:

<b>mf<sub>x</sub>er rD</b>	equivalent to	<b>mf<sub>spr</sub> rD,1</b>
<b>mflr rD</b>	equivalent to	<b>mf<sub>spr</sub> rD,8</b>
<b>mfctr rD</b>	equivalent to	<b>mf<sub>spr</sub> rD,9</b>

In the PowerPC OEA, the SPR field denotes a special-purpose register, encoded as shown in Table 10. The contents of the designated SPR are placed into rD. SPR[0] = 1 if and only if reading the register is supervisor-level. Execution of this instruction specifying a defined and supervisor-level register when MSR[PR] = 1 will result in a privileged instruction type program exception.

If MSR[PR] = 1, the only effect of executing an instruction with an SPR number that is not shown in Table 10 and has SPR[0] = 1 is to cause a supervisor-level instruction type program exception or an illegal instruction type program exception. For all other cases, MSR[PR] = 0 or SPR[0] = 0. If the SPR field contains any value that is not shown in Table 10, either an illegal instruction type program exception occurs or the results are boundedly undefined.

Other registers altered:

<sup>1</sup>Note that the order of the two 5-bit halves of the SPR number is reversed compared with actual instruction coding.

<sup>2</sup>Sets EE Bit (Bit 16) in MSR.

<sup>3</sup>Clears EE Bit (Bit 16) in MSR.

<sup>4</sup>Development Support (Debug) Register.

For **mtspr** and **mfspr** instructions, the SPR number coded in assembly language does not appear directly as a 10-bit binary number in the instruction. The number coded is split into two 5-bit halves that are reversed in the instruction, with the high-order five bits appearing in bits 16–20 of the instruction and the low-order five bits in bits 11–15.

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA/OEA	√*		XFX

\* Note that **mfspr** is supervisor-level only if SPR[0] = 1.

**mfsr**

mfsr rD,SR

|----------------------------|------------------|----------|------|
| OEA                        | √                |          | X    |

# mfsrin

Move from Segment Register Indirect

# mfsrin

**mfsrin**

**rD,rB**

 Reserved

$rD \leftarrow \text{SEGREG}(rB[0-3])$

The contents of the segment register selected by bits 0–3 of rB are copied into rD. This is a supervisor-level instruction.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
OEA	√		X

mftb

rD,TBR

 Reserved

**\*Note:** This is a split field.

```

n ← tbr[5–9] || tbr[0–4]
if n = 268 then

rD ← TBL

else if n = 269 then

rD ← TBU

```

**Table 11. TBR Encodings for mftb**

TBR*			Register Name	Access
Decimal	tbr[5–9]	tbr[0–4]		
268	01000	01100	TB Read	User
269	01000	01101	TBU Read	User

\*Note that the order of the two 5-bit halves of the TBR number is reversed.

If the TBR field contains any value other than one of the values shown in Table 11, then one of the following occurs:

- The system illegal instruction error handler is invoked.
- The system supervisor-level instruction error handler is invoked.
- The results are boundedly undefined.

It is important to note that some implementations may implement **mftb** and **mfspir** identically, therefore, a TBR number must not match an SPR number.

Other registers altered:

- None

Simplified mnemonics:

**mftb** rD

equivalent to

**mftb** rD,268

**mftbu** rD

equivalent to

**mftb** rD,269

PowerPC Architecture Level	Supervisor Level	Optional	Form
VEA			XFX

**mtcrf**

CRM,rS

 Reserved

$$\text{mask} \leftarrow (4)(\text{CRM}[0]) \mid (4)(\text{CRM}[1]) \mid \dots (4)(\text{CRM}[7])$$

$$\text{CR} \leftarrow (\text{rS} \ \& \ \text{mask}) \mid (\text{CR} \ \& \ \neg \text{mask})$$

The contents of **rS** are placed into the condition register under control of the field mask specified by CRM. The field mask identifies the 4-bit fields affected. Let *i* be an integer in the range 0–7. If CRM(*i*) = 1, CR field *i* (CR bits 4 \* *i* through 4 \* *i* + 3) is set to the contents of the corresponding field of **rS**.

Note that updating a subset of the eight fields of the condition register may have substantially poorer performance on some implementations than updating all of the fields.

Other registers altered:

- CR fields selected by mask

Simplified mnemonics:

**mtcr** **rS**

equivalent to

**mtcrf** 0xFF,rS

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			XFX

# mtmsr

Move to Machine State Register

# mtmsr

**mtmsr**

**rS**

 Reserved

$MSR \leftarrow (rS)$

The contents of **rS** are placed into the MSR. This is a supervisor-level instruction. It is also an execution synchronizing instruction except with respect to alterations to the POW and LE bits.

In addition, alterations to the MSR[EE] and MSR[RI] bits are effective as soon as the instruction completes. Thus if MSR[EE] = 0 and an external or decremter exception is pending, executing an **mtmsr** instruction that sets MSR[EE] = 1 will cause the external or decremter exception to be taken before the next instruction is executed, if no higher priority exception exists.

Other registers altered:

- MSR

PowerPC Architecture Level	Supervisor Level	Optional	Form
OEA	√		X

# mtspr

Move to Special-Purpose Register

# mtspr

mtspr

SPR,rS

 Reserved

**\*Note:** This is a split field.

$$n \leftarrow \text{spr}[5-9] \parallel \text{spr}[0-4]$$

$$\underline{\underline{\text{SPR}(n) \leftarrow \text{rS}}}$$

In the PowerPC UISA, the SPR field denotes a special-purpose register, encoded as shown in Table 12. The contents of rS are placed into the designated special-purpose register.

**Table 12. PowerPC UISA SPR Encodings for mtspr**

SPR**			Register Name
Decimal	spr[5–9]	spr[0–4]	
1	00000	00001	XER
8	00000	01000	LR
9	00000	01001	CTR

\*\* Note that the order of the two 5-bit halves of the SPR number is reversed compared with actual instruction coding.

If the SPR field contains any value other than one of the values shown in Table 12, and the processor is operating in user mode, one of the following occurs:

- The system illegal instruction error handler is invoked.
- The system supervisor instruction error handler is invoked.
- The results are boundedly undefined.

Other registers altered:

- See Table 12.

Simplified mnemonics:

<b>mtxer rD</b>	equivalent to	<b>mtspr 1,rD</b>
<b>mtlr rD</b>	equivalent to	<b>mtspr 8,rD</b>
<b>mtctr rD</b>	equivalent to	<b>mtspr 9,rD</b>

In the PowerPC OEA, the SPR field denotes a special-purpose register, encoded as shown in Table 13. The contents of rS are placed into the designated special-purpose register. For this instruction, SPRs TBL and TBU are treated as separate 32-bit registers; setting one leaves the other unaltered.

The value of SPR[0] = 1 if and only if writing the register is a supervisor-level operation. Execution of this instruction specifying a defined and supervisor-level register when MSR[PR] = 1 results in a privileged instruction type program exception.

If MSR[PR] = 1 then the only effect of executing an instruction with an SPR number that is not shown in Table 13 and has SPR[0] = 1 is to cause a privileged instruction type program exception or an illegal instruction type program exception. For all other cases, MSR[PR] = 0 or SPR[0] = 0, if the SPR field contains any value that is not shown in Table 13, either an illegal instruction type program exception occurs or the results are boundedly undefined.

Other registers altered:

- See Table 13.

$MSR[16-23, 25-27, 30-31] \leftarrow SRR1[16-23, 25-27, 30-31]$

$NIA \leftarrow \text{iea } SRR0[0-29] \parallel 0b00$

Bits SRR1[0,5-9,16-31] are placed into the corresponding bits of the MSR. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address SRR0[0-29] || 0b00. If the new MSR value enables one or more pending exceptions, the exception associated with the highest priority pending exception is generated; in this case the value placed into SRR0 by the exception processing mechanism is the address of the instruction that would have been executed next had the exception not occurred. Note that an implementation may define additional MSR bits, and in this case, may also cause them to be saved to SRR1 from MSR on an exception and restored to MSR from SRR1 on an **rfi**. This is a supervisor-level, context synchronizing instruction.

Rotate Left Word Immediate then Mask Insert

**rlwimi**            **rA,rS,SH,MB,ME**            (**Rc = 0**)**rlwimi.**            **rA,rS,SH,MB,ME**            (**Rc = 1**)

20	S	A	SH	MB	ME	Rc
0	5 6	10 11	15 16	20 21	25 26	30 31

```

n ← SH
r ← ROTL(rS, n)
m ← MASK(MB, ME)
rA ← (r & m) | (rA & ¬ m)

```

The contents of **rS** are rotated left the number of bits specified by operand **SH**. A mask is generated having 1 bits from bit **MB** through bit **ME** and 0 bits elsewhere. The rotated data is inserted into **rA** under control of the generated mask.

Note that **rlwimi** can be used to insert a bit field into the contents of **rA** using the methods shown below:

- To insert an  $n$ -bit field, that is left-justified **rS**, into **rA** starting at bit position  $b$ , set  $SH = 32 - b$ ,  $MB = b$ , and  $ME = (b + n) - 1$ .
- To insert an  $n$ -bit field, that is right-justified in **rS**, into **rA** starting at bit position  $b$ , set  $SH = 32 - (b + n)$ ,  $MB = b$ , and  $ME = (b + n) - 1$ .

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO(if **Rc = 1**)

Simplified mnemonics:

**inslwi** **rA,rS,n,b**            equivalent to **rlwimi**            **rA,rS,32 - b,b,b + n - 1**  
**insrwi** **rA,rS,n,b** ( $n > 0$ )            equivalent to **rlwimi**            **rA,rS,32 - (b + n),b,(b + n) - 1**

# rlwinm<sub>x</sub>

# rlwinm<sub>x</sub>

Rotate Left Word Immediate then AND with Mask

**rlwinm**                      **rA,rS,SH,MB,ME**                      (**Rc** = 0)

**rlwinm.**                      **rA,rS,SH,MB,ME**                      (**Rc** = 1)

21	S	A	SH	MB	ME	Rc
0	5 6	10 11	15 16	20 21	25 26	30 31

```

n ← SH
r ← ROTL(rS, n)
m ← MASK(MB, ME)
rA ← r & m

```

The contents of **rS** are rotated left the number of bits specified by operand **SH**. A mask is generated having 1 bits from bit **MB** through bit **ME** and 0 bits elsewhere. The rotated data is ANDed with the generated mask and the result is placed into **rA**.

Note that **rlwinm** can be used to extract, rotate, shift, and clear bit fields using the methods shown below:

- To extract an  $n$ -bit field, that starts at bit position  $b$  in **rS**, right-justified into **rA** (clearing the remaining  $32 - n$  bits of **rA**), set **SH** =  $b + n$ , **MB** =  $32 - n$ , and **ME** = 31.
- To extract an  $n$ -bit field, that starts at bit position  $b$  in **rS**, left-justified into **rA** (clearing the remaining  $32 - n$  bits of **rA**), set **SH** =  $b$ , **MB** = 0, and **ME** =  $n - 1$ .
- To rotate the contents of a register left (or right) by  $n$  bits, set **SH** =  $n$  ( $32 - n$ ), **MB** = 0, and **ME** = 31.
- To shift the contents of a register right by  $n$  bits, by setting **SH** =  $32 - n$ , **MB** =  $n$ , and **ME** = 31. It can be used to clear the high-order  $b$  bits of a register and then shift the result left by  $n$  bits by setting **SH** =  $n$ , **MB** =  $b - n$  and **ME** =  $31 - n$ .
- To clear the low-order  $n$  bits of a register, by setting **SH** = 0, **MB** = 0, and **ME** =  $31 - n$ .

# SC

## System Call

# SC

Reserved

The **sc** instruction calls the operating system to perform a service. When control is returned to the program that executed the system call, the content of the registers depends on the register conventions used by the program providing the system service.

The effective address of the instruction following the **sc** instruction is placed into SRR0. Bits 0, 5-9, and 16-31 of the MSR are placed into the corresponding bits of SRR1, and bits 1-4 and 10-15 of SRR1 are set to undefined values. An **sc** exception is generated. The exception alters the MSR. The exception causes the next instruction to be fetched from offset 0xC00 from the base real address indicated by the new setting of MSR[IP].

Other registers altered:

- Dependent on the system service
- SRR0
- SRR1
- MSR

# sraw<sub>x</sub>

Shift Right Algebraic Word

# sraw<sub>x</sub>

**sraw**                                      rA,rS,rB                                      (Rc = 0)

**sraw.**                                      rA,rS,rB                                      (Rc = 1)

$n \leftarrow \text{rB}[27-31]$   
 $\text{rA} \leftarrow \text{ROTL}(\text{rS}, n)$

If  $\text{rB}[26] = 0$ , then the contents of rS are shifted right the number of bits specified by  $\text{rB}[27-31]$ . Bits shifted out of position 31 are lost. The result is padded on the left with sign bits before being placed into rA. If  $\text{rB}[26] = 1$ , then rA is filled with 32 sign bits (bit 0) from rS. CR0 is set based on the value written into rA. XER[CA] is set if rS contains a negative number and any 1 bits are shifted out of position 31; otherwise XER[CA] is cleared. A shift amount of zero causes XER[CA] to be cleared.

Note that the **sraw** instruction, followed by **addze**, can be used to divide quickly by  $2^n$ . The setting of the XER[CA] bit, by **sraw**, is independent of mode.

Other registers altered:

- Condition Register (CR0 field):  
Affected: LT, GT, EQ, SO(if Rc = 1)
- XER:  
Affected: CA

# sync

Synchronize

# sync

☐ Reserved

31	00 000	0 0000	0000 0	598	0
0	5 6	10 11	15 16	20 21	30 31

The **sync** instruction provides an ordering function for the effects of all instructions executed by a given processor. Executing a **sync** instruction ensures that all instructions preceding the **sync** instruction appear to have completed before the **sync** instruction completes, and that no subsequent instructions are initiated by the processor until after the **sync** instruction completes. When the **sync** instruction completes, all external accesses caused by instructions preceding the **sync** instruction will have been performed with respect to all other mechanisms that access memory.

Multiprocessor implementations also send a **sync** address-only broadcast that is useful in some designs. For example, if a design has an external buffer that re-orders loads and stores for better bus efficiency, the **sync** broadcast signals to that buffer that previous loads/stores must be completed before any following loads/stores.

The **sync** instruction can be used to ensure that the results of all stores into a data structure, caused by store instructions executed in a “critical section” of a program, are seen by other processors before the data structure is seen as unlocked.

The functions performed by the **sync** instruction will normally take a significant amount of time to complete, so indiscriminate use of this instruction may adversely affect performance. In addition, the time required to execute **sync** may vary from one execution to another. The **eieio** instruction may be more appropriate than **sync** for many cases.

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
UISA			X

tlbia

tlbia

Translation Lookaside Buffer Invalidate All

All TLB entries ← invalid

The entire *translation lookaside buffer (TLB)* is invalidated (that is, all entries are removed). The TLB is invalidated regardless of the settings of MSR[IR] and MSR[DR]. The invalidation is done without reference to the SLB, segment table, or segment registers. This instruction does not cause the entries to be invalidated in other processors. This is a supervisor-level instruction.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
OEA	√	√	X

tlbie

tlbie

Translation Lookaside Buffer Invalidate Entry

```
VPS ← rB[4-19]
Identify TLB entries corresponding to VPS
Each such TLB entry ← invalid
```

EA is the contents of rB. If the translation lookaside buffer (TLB) contains an entry corresponding to EA, that entry is made invalid (that is, removed from the TLB).

*Multiprocessing* implementations (for example, the 601, and 604) send a **tlbie** address-only broadcast over the address bus to tell other processors to invalidate the same TLB entry in their TLBs.

The TLB search is done regardless of the settings of MSR[IR] and MSR[DR]. The search is done based on a portion of the logical page number within a segment, without reference to the segment registers. All entries matching the search criteria are invalidated.

Block address translation for EA, if any, is ignored.

This is a supervisor-level instruction.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
OEA	√	√	X

tlbsync

TLB Synchronize

tlbsync

If an implementation sends a broadcast for **tlbie** then it will also send a broadcast for **tlbsync**. Executing a **tlbsync** instruction ensures that all **tlbie** instructions previously executed by the processor executing the **tlbsync** instruction have completed on all other processors. The operation performed by this instruction is treated as a caching-inhibited and guarded data access with respect to the ordering done by **eiemo**. This instruction is supervisor-level.

Other registers altered:

- None

PowerPC Architecture Level	Supervisor Level	Optional	Form
OEA	√	√	X

twTO,rA,rB

```
a ← EXTS(rA)
b ← EXTS(rB)
if (a < b) & TO[0] then TRAP
if (a > b) & TO[1] then TRAP
if (a = b) & TO[2] then TRAP
if (a <U b) & TO[3] then TRAP
if (a >U b) & TO[4] then TRAP
```

The contents of **rA** are compared with the contents of **rB**. If any bit in the **TO** field is set and its corresponding condition is met by the result of the comparison, then the system trap handler is invoked.

- Other registers altered:
- None

Simplified mnemonics:

<b>tweq</b> rA,rB	equivalent to	<b>tw</b> 4,rA,rB
<b>twlge</b> rA,rB	equivalent to	<b>tw</b> 5,rA,rB
<b>trap</b>	equivalent to	<b>tw</b> 31,0,0

# Appendix

## MPCxxx Instruction Set Listings

This appendix lists the MPCxxx's instruction set. Instructions are sorted by *mnemonic*, opcode, function, and form. Also included in this appendix is a quick reference table that contains general information, such as the architecture level, privilege level, and form.

Note that split fields, which represent the concatenation of sequences from left to right, are shown in lowercase.

### Instructions Sorted by Mnemonic

Table 1 lists the instructions implemented in the MPCxxx in alphabetical order by mnemonic.

Key:

<sup>1</sup> Supervisor-level instruction  
<sup>2</sup> Supervisor- and user-level instruction  
<sup>3</sup> Load and store string or multiple instruction  
<sup>4</sup> PowerPC Optional instruction

# Instruction Set Legend

Table 33 provides general information on the MPCxxx instruction set (such as the architectural level, privilege level, and form).

**Table 33. MPCxxx Instruction Set Legend**

	UISA	VEA	OEA	Supervisor Level		Optional	Form
<b>addx</b>	√						XO
<b>addcx</b>	√						XO
<b>addex</b>	√						XO
